Audit Findings	14

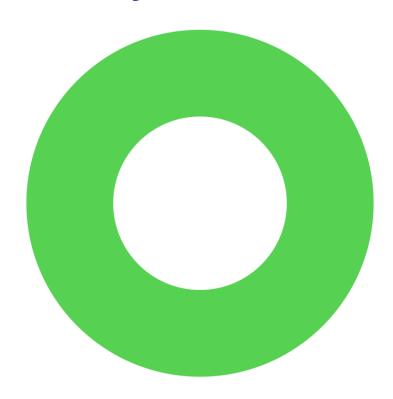

## **Management Summary**

GoodDollar contacted Sayfer to perform a security audit on their bridge on-chain smart contracts and off-chain agents.

This report documents the research carried out by Sayfer targeting the selected resources defined under the research scope. Particularly, this report displays the security posture review for GoodDollar bridge on-chain smart contracts and off-chain agents.

Over the audit period of 4 weeks, we discovered 0 vulnerabilities in the codebase. We found that all the bridge components have a clean and well-structured code, and after deep and thorough research we haven't found any security issues.

## **Vulnerabilities by Risk**

Risk	Informational	Low	Medium	High	Critical
# of issues	0	0	0	0	0

- **Critical** Immediate or ongoing part of the business being exploited with direct key business losses.
- High Direct threat to key business processes.
- Medium Indirect threat to key business processes or partial threat to business processes.
- Low No direct threat exists. The vulnerability may be exploited using other vulnerabilities.
- **Informational** This finding does not indicate vulnerability, but states a comment that notifies about design flaws and improper implementation that might cause a problem in the long run.

## **Approach**

#### Introduction

GoodDollar contacted Sayfer to perform a security audit on the bridge component.

This report documents the research carried out by Sayfer targeting the selected resources defined under the research scope. Particularly, this report displays the security posture review for the aforementioned contracts.

#### **Scope Overview**

Together with the GoodDollar team we define that the scope of the project will be:

1. GoodDollar bridge, including off-chain agent and on-chain smart contract on this repository up to commit b41c9d6703434be7fbdd89d7b757904757f3b8e0

Our tests were performed between November 11th to December 11th, 2022.

#### **Scope Validation**

We began by ensuring that the scope defined to us by the client was technically logical. Deciding what scope is right for a given system is part of the initial discussion.

#### **Threat Model**

We defined that the largest current threat to the system is the ability of malicious users to steal funds from the on-chain or off-chain code.

### **Protocol Overview**

#### **Protocol Introduction**

The GoodDollar protocol is a community-driven, distributed framework designed to generate, fund, and distribute global basic income via the GoodDollar token (hereafter "G\$"). G\$ is an ERC-20 digital asset built on the Ethereum blockchain that operates within the emerging ecosystem of decentralized and open finance. GoodDollar leverages new protocols and smart contracts across the ecosystem to deliver its basic income economy.

# **Security Evaluation**

The following test cases were the guideline while auditing the system. This checklist is a modified version of the SCSVS v1.2, with improved grammar, clarity, conciseness, and additional criteria. Where there is a gap in the numbering, an original criterion was removed. Criteria that are marked with an asterisk were added by us.

Architecture, Design and Threat Modeling	Test Name
G1.2	Every introduced design change is preceded by threat modeling.
G1.3	The documentation clearly and precisely defines all trust boundaries in the contract (trusted relations with other contracts and significant data flows).
G1.4	The SCSVS, security requirements or policy is available to all developers and testers.
G1.5	The events for the (state changing/crucial for business) operations are defined.
G1.6	The project includes a mechanism that can temporarily stop sensitive functionalities in case of an attack. This mechanism should not block users' access to their assets (e.g. tokens).
G1.7	The amount of unused cryptocurrencies kept on the contract is controlled and at the minimum acceptable level so as not to become a potential target of an attack.
G1.8	If the fallback function can be called by anyone, it is included in the threat model.
G1.9	Business logic is consistent. Important changes in the logic should be applied in all contracts.
G1.10	Automatic code analysis tools are employed to detect vulnerabilities.
G1.11	The latest major release of Solidity is used.
G1.12	When using an external implementation of a contract, the most recent version is used.
G1.13	When functions are overridden to extend functionality, the super keyword is used to maintain previous functionality.
G1.14	The order of inheritance is carefully specified.
G1.15	There is a component that monitors contract activity using events.
G1.16	The threat model includes whale transactions.
G1.17	The leakage of one private key does not compromise the security of the entire project.

Policies and Procedures	Test Name
G2.2	The system's security is under constant monitoring (e.g. the expected level of

	funds).
G2.3	There is a policy to track new security vulnerabilities and to update libraries to the
	latest secure version.
G2.4	The security department can be publicly contacted and that the procedure for
G2.4	handling reported bugs (e.g., thorough bug bounty) is well-defined.
G2.5	The process of adding new components to the system is well defined.
G2.6	The process of major system changes involves threat modeling by an external
G2.0	company.
G2.7	The process of adding and updating components to the system includes a security
G2.7	audit by an external company.
G2.8	In the event of a hack, there's a clear and well known mitigation procedure in place.
G2.9	The procedure in the event of a hack clearly defines which persons are to execute
	the required actions.
G2.10	The procedure includes alarming other projects about the hack through trusted
	channels.
G2.11	A private key leak mitigation procedure is defined.

Upgradability	Test Name
G2.2	Before upgrading, an emulation is made in a fork of the main network and
	everything works as expected on the local copy.
G2.3	The upgrade process is executed by a multisig contract where more than one
G2.5	person must approve the operation.
	Timelocks are used for important operations so that the users have time to
G2.4	observe upcoming changes (please note that removing potential vulnerabilities in
	this case may be more difficult).
G2.5	initialize() can only be called once.
G2.6	initialize() can only be called by an authorized role through appropriate modifiers
G2.0	(e.g. initializer, onlyOwner).
G2.7	The update process is done in a single transaction so that no one can front-run it.
G2.8	Upgradeable contracts have reserved gap on slots to prevent overwriting.
G2.9	The number of reserved (as a gap) slots has been reduced appropriately if new
G2.9	variables have been added.
G2.10	There are no changes in the order in which the contract state variables are
G2.10	declared, nor their types.
G2.11	New values returned by the functions are the same as in previous versions of the
	contract (e.g. owner(), balanceOf(address)).
G2.12	The implementation is initialized.
G2.13	The implementation can't be destroyed.

<b>Business Logic</b>	Test Name
G4.2	The contract logic and protocol parameters implementation corresponds to the
	documentation.
G4.3	The business logic proceeds in a sequential step order and it is not possible to skip
G4.5	steps or to do it in a different order than designed.
G4.4	The contract has correctly enforced business limits.
C 4 F	The business logic does not rely on the values retrieved from untrusted contracts
G4.5	(especially when there are multiple calls to the same contract in a single flow).
G4.6	The business logic does not rely on the contract's balance (e.g., balance == 0).
G4.7	Sensitive operations do not depend on block data (e.g., block hash, timestamp).
G4.8	The contract uses mechanisms that mitigate transaction-ordering (front-running)
	attacks (e.g. pre-commit schemes).
G4.9	The contract does not send funds automatically, but lets users withdraw funds in
	separate transactions instead.

Access Control	Test Name
G5.2	The principle of the least privilege is upheld. Other contracts should only be able to
	access functions and data for which they possess specific authorization.
	New contracts with access to the audited contract adhere to the principle of
G5.3	minimum rights by default. Contracts should have a minimal or no permissions
	until access to the new features is explicitly granted.
G5.4	The creator of the contract complies with the principle of the least privilege and
d5.4	their rights strictly follow those outlined in the documentation.
G5.5	The contract enforces the access control rules specified in a trusted contract,
05.5	especially if the dApp client-side access control is present and could be bypassed.
G5.6	Calls to external contracts are only allowed if necessary.
G5.7	Modifier code is clear and simple. The logic should not contain external calls to
d3.7	untrusted contracts.
G5.8	All user and data attributes used by access controls are kept in trusted contracts
	and cannot be manipulated by other contracts unless specifically authorized.
G5.9	the access controls fail securely, including when a revert occurs.
G5.10	If the input (function parameters) is validated, the positive validation approach
	(whitelisting) is used where possible.

Communication	Test Name
G6.2	Libraries that are not part of the application (but the smart contract relies on to operate) are identified.
G6.3	Delegate call is not used with untrusted contracts.

G6.4	Third party contracts do not shadow special functions (e.g. revert).
G6.5	The contract does not check whether the address is a contract using <i>extcodesize</i>
	opcode.
	Re-entrancy attacks are mitigated by blocking recursive calls from other contracts
G6.6	and following the Check-Effects-Interactions pattern. Do not use the send function
	unless it is a must.
G6.7	The result of low-level function calls (e.g. send, delegatecall, call) from other
	contracts is checked.
G6.8	Contract relies on the data provided by the right sender and does not rely on
	tx.origin value.

Arithmetic	Test Name
G7.2	The values and math operations are resistant to integer overflows. Use SafeMath
	library for arithmetic operations before solidity 0.8.*.
G7.3	the unchecked code snippets from Solidity ≥ 0.8.* do not introduce integer
G7.5	under/overflows.
G7.4	Extreme values (e.g. maximum and minimum values of the variable type) are
G7.4	considered and do not change the logic flow of the contract.
G7.5	Non-strict inequality is used for balance equality.
G7.6	Correct orders of magnitude are used in the calculations.
G7.7	In calculations, multiplication is performed before division for accuracy.
G7.8	The contract does not assume fixed-point precision and uses a multiplier or store
	both the numerator and denominator.

Denial of Service	Test Name
G8.2	The contract does not iterate over unbound loops.
G8.3	Self-destruct functionality is used only if necessary. If it is included in the contract, it
	should be clearly described in the documentation.
G8.4	The business logic isn't blocked if an actor (e.g. contract, account, oracle) is absent.
G8.5	The business logic does not disincentivize users to use contracts (e.g. the cost of
G6.5	transaction is higher than the profit).
G8.6	Expressions of functions assert or require have a passing variant.
G8.7	If the fallback function is not callable by anyone, it is not blocking contract
G6.7	functionalities.
G8.8	There are no costly operations in a loop.
G8.9	There are no calls to untrusted contracts in a loop.
G8.10	If there is a possibility of suspending the operation of the contract, it is also
	possible to resume it.
G8.11	If whitelists and blacklists are used, they do not interfere with normal operation of

	the system.
G8.12	There is no DoS caused by overflows and underflows.

Blockchain Data	Test Name
G9.2	Any saved data in contracts is not considered secure or private (even private
	variables).
G9.3	No confidential data is stored in the blockchain (passwords, personal data, token
G9.5	etc.).
C0.4	Contracts do not use string literals as keys for mappings. Global constants are used
G9.4	instead to prevent Homoglyph attack.
G9.5	Contract does not trivially generate pseudorandom numbers based on the
G9.5	information from blockchain (e.g. seeding with the block number).

Gas Usage and Limitations	Test Name
G10.2	Gas usage is anticipated, defined and has clear limitations that cannot be exceeded. Both code structure and malicious input should not cause gas exhaustion.
G10.3	Function execution and functionality does not depend on hard-coded gas fees (they are bound to vary).

Clarity and Readability	Test Name
G11.2	The logic is clear and modularized in multiple simple contracts and functions.
G11.3	Each contract has a short 1-2 sentence comment that explains its purpose and functionality.
G11.4	Off-the-shelf implementations are used, this is made clear in comment. If these implementations have been modified, the modifications are noted throughout the contract.
G11.5	The inheritance order is taken into account in contracts that use multiple inheritance and shadow functions.
G11.6	Where possible, contracts use existing tested code (e.g. token contracts or mechanisms like <i>ownable</i> ) instead of implementing their own.
G11.7	Consistent naming patterns are followed throughout the project.
G11.8	Variables have distinctive names.
G11.9	All storage variables are initialized.
G11.10	Functions with specified return type return a value of that type.
G11.11	All functions and variables are used.
G11.12	require is used instead of revert in if statements.

C11 12	The assert function is used to test for internal errors and the require function is
G11.13	used to ensure a valid condition in input from users and external contracts.
G11.14	Assembly code is only used if necessary.

Test Coverage	Test Name
G12.2	Abuse narratives detailed in the threat model are covered by unit tests.
G12.3	Sensitive functions in verified contracts are covered with tests in the development
G12.3	phase.
G12.4	Implementation of verified contracts has been checked for security vulnerabilities
G12.4	using both static and dynamic analysis.
G12.5	Contract specification has been formally verified.
G12.6	The specification and results of the formal verification is included in the
G12.0	documentation.

Decentralized Finance	Test Name
G14.1	The lender's contract does not assume its balance (used to confirm loan
G14.1	repayment) to be changed only with its own functions.
	Functions that change lenders' balance and/or lend cryptocurrency are non-re-
G14.2	entrant if the smart contract allows borrowing the main platform's cryptocurrency
014.2	(e.g. Ethereum). It blocks the attacks that update the borrower's balance during the
	flash loan execution.
	Flash loan functions can only call predefined functions on the receiving contract. If
G14.3	it is possible, define a trusted subset of contracts to be called. Usually, the sending
	(borrowing) contract is the one to be called back.
	If it includes potentially dangerous operations (e.g. sending back more ETH/tokens
G14.4	than borrowed), the receiver's function that handles borrowed ETH or tokens can
014.4	be called only by the pool and within a process initiated by the receiving contract's
	owner or another trusted source (e.g. multisig).
	Calculations of liquidity pool share are performed with the highest possible
G14.5	precision (e.g. if the contribution is calculated for ETH it should be done with 18
G14.5	digit precision - for Wei, not Ether). The dividend must be multiplied by the 10 to
	the power of the number of decimal digits (e.g. dividend * 10^18 / divisor).
	Rewards cannot be calculated and distributed within the same function call that
G14.6	deposits tokens (it should also be defined as non-re-entrant). This protects from
	momentary fluctuations in shares.
	Governance contracts are protected from flash loan attacks. One possible
G14.7	mitigation technique is to require the process of depositing governance tokens and
	proposing a change to be executed in different transactions included in different

	blocks.
G14.8	When using on-chain oracles, contracts are able to pause operations based on the
014.8	oracles' result (in case of a compromised oracle).
	External contracts (even trusted ones) that are allowed to change the attributes of
G14.9	a project contract (e.g. token price) have the following limitations implemented:
G14.9	thresholds for the change (e.g. no more/less than 5%) and a limit of updates (e.g.
	one update per day).
	Contract attributes that can be updated by the external contracts (even trusted
G14.10	ones) are monitored (e.g. using events) and an incident response procedure is
	implemented (e.g. during an ongoing attack).
G14.11	Complex math operations that consist of both multiplication and division
G14.11	operations first perform multiplications and then division.
	When calculating exchange prices (e.g. ETH to token or vice versa), the numerator
G14.12	and denominator are multiplied by the reserves (see the <code>getInputPrice</code> function in
	the <i>UniswapExchange</i> contract).

# **Audit Findings**

While conducting the audit on both bridge on-chain smart contracts and off-chain agents, we found that all the bridge components have a clean and well-structured code, and after deep and thorough research we haven't found any security issues.
